

Question 1 :- Explain the purpose of using the var() function in css.

Answer - The var() function in CSS is used to insert the value of a CSS variable into a property value. The var() function can't be used in property names or selectors.

Here are some reasons why the var() function is useful:

#### Reusable colors

You can use variables to store colors instead of copying and pasting them throughout your design.

#### Reusable spacing

You can define common spacing units to use across your stylesheets.

#### Global or local scope

You can create variables with either global or local scope. Global variables can be used throughout the document, while local variables are only used within the selector where they are declared.

#### Change values easily

You can change the value of a variable in one place, and that change will apply everywhere the variable is used.
